Current comparison of throughfall samlers in FUTMON -One step forward in a harmonisation

Comparison of througfall samlers in FUTMON

16 out of 17 sample bottles are hanging freely in the air

Does it matter for quality how we install?

other ways

Samples to be kept dark and cold – Why?

- to avoid algal growth and uptake of nitrogen by their growth
- to slow down microbial or chemical degradation of the sample
- to avoid transformations of nitrogen compounds, that is especially nitrification transforming ammonium to nitrate – especially a problem in agricultural areas

Nitrification

- Nitrification is a two-step process. Bacteria known as *Nitrosomonas* convert ammonium to nitrite. Next, bacteria called *Nitrobacter* finish the conversion of nitrite to nitrate. The reactions are generally coupled and proceed rapidly to the nitrate form.
- These bacteria known as "nitrifiers" are strict "aerobes," meaning they must have free dissolved oxygen to perform their work. Nitrification occurs only under aerobic conditions at dissolved oxygen levels of 1.0 mg/L or more.

Nitrification in water samples

- A sufficient population of nitrifying bacteria must be present in order to nitrify. These bacteria are attached growth organisms, meaning that they must attach themselves to the surface of an object. It is believed that nitrifiers may attach to the sides of the container, to particles in the sample and perhaps to algae particles.
- Nitrification stops at a pH below 6.0.
- High temperatures promote and increase nitrification - as the temperature increases, the nitrification rate increases to a certain degree. If nitrification is lost, it will not resume until the temperature increases to well over 10°C.

The dependence of nitrifiers on temperature

Gerardi (2002): Temperature and nitrification

Temperature	Effect upon nitrification
> 45°C	Nitrification ceases
28-32°C	Optimal temperature range
16°C	Approx. 50% of nitrafication rate at 30°C
10°C	Significant reduction in rate, approx. 20% of nitrafication rate at 30°C
< 5°C	Nitrification ceases

Temperature in samplers hanging free in the air >< in soil pit

Conclusion:

We should cool samples – Sampler in soil pit is a solution, but:

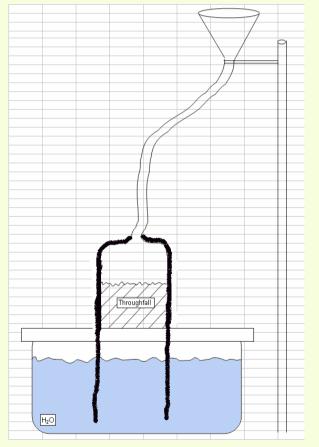

Countries do not want to dig soil pits!

We might then need another way to cool samples in the field

Temperature in sampler cooled by water evaporation - development

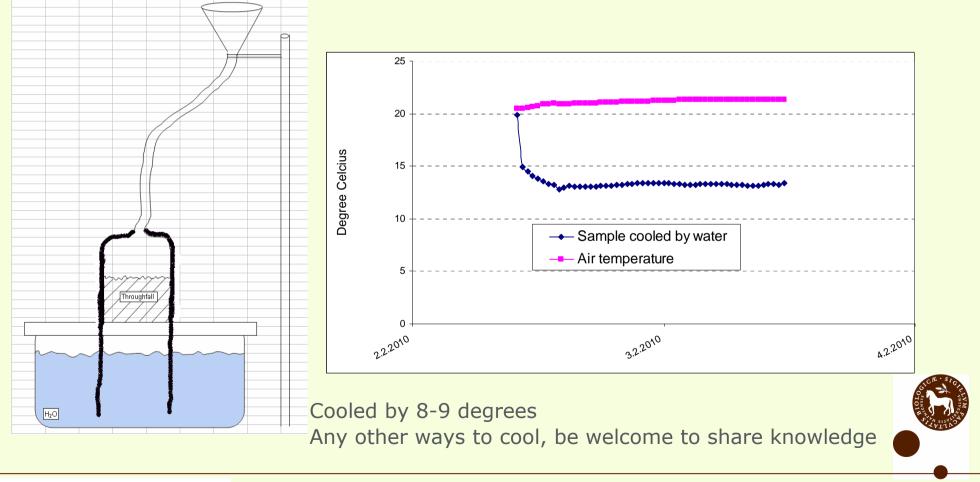

- A self-cooling system where evaporation of water from a cloth, soaked in water and wrapped around the sample flask, will cool the sample
- Non-destructable you do not need to dig soil pits. You can place the system above ground
- Maybe not feasible in Mediterranean areas with high temperatures and little precipitation?

Temperature in sampler cooled by water – a test in the laboratory

Future throughfall comparison experiment in Denmark

- Use of the Slovenian throughfall samplers
- 1 sampler hanging free in the air (as most are in FUTMON), 1 sampler in a soil pit, and 1 sampler cooled by water
- All three samplers placed as close as possible to each other in the forest
- 10 replications a total of 30 samplers
- Running for 4 months during the summer 2010 measuring fortnightly
- Temperature is measured in 3x3 samplers and in the air
- Nitrogen compounds alone will be measured (nitrate, ammonium and organic nitrogen)

Alike experiments in other countries?

- Any other temperature experiments in throughfall samples performed? - please contact us!
- If you should be interested in taking part in this kind of experiment and publishing it afterwards
 please contact us!
